Heatwaves in Australia now

- Heatwaves are the most **deadly natural hazard** (Coates 2014)
- Cooling demand drives **peak electricity demand** (Australian Electricity Market Operator, 2011), contributing to soaring **electricity prices** and **energy poverty**
- **Air-conditioning (AC)** is one of the **most frequently used adaptation** techniques
- **Negative impacts** of AC:
  - Increased carbon emission
  - Increased dependence on it (Candido, 2010)
  - Warming up the outdoors

Framework for the population heat stress resilience

Methods

1. Impacts

Time-series and regression analyses in Adelaide and Sydney

Daily data of: electricity consumption, demand; water demand and morbidity

2. Population resilience

Online survey

Representative sample from Adelaide (N=393) and questions about: demography, built environment, retrofitting activity, adaptation, heat-related health problems.

3. Heat stress resistance of buildings

Results, online survey on heat stress resilience

- The **health of one fifth** of the population was impacted by a medium heatwave.
- **Three quarters of dwellings** were reported having insufficient heat stress resistance.
- **Tenants** tended to have more health issues and live in less heat stress resistant homes
- Homes with roof insulation had less health issues
- >>>
  Implement
  the Energy Performance Certificate

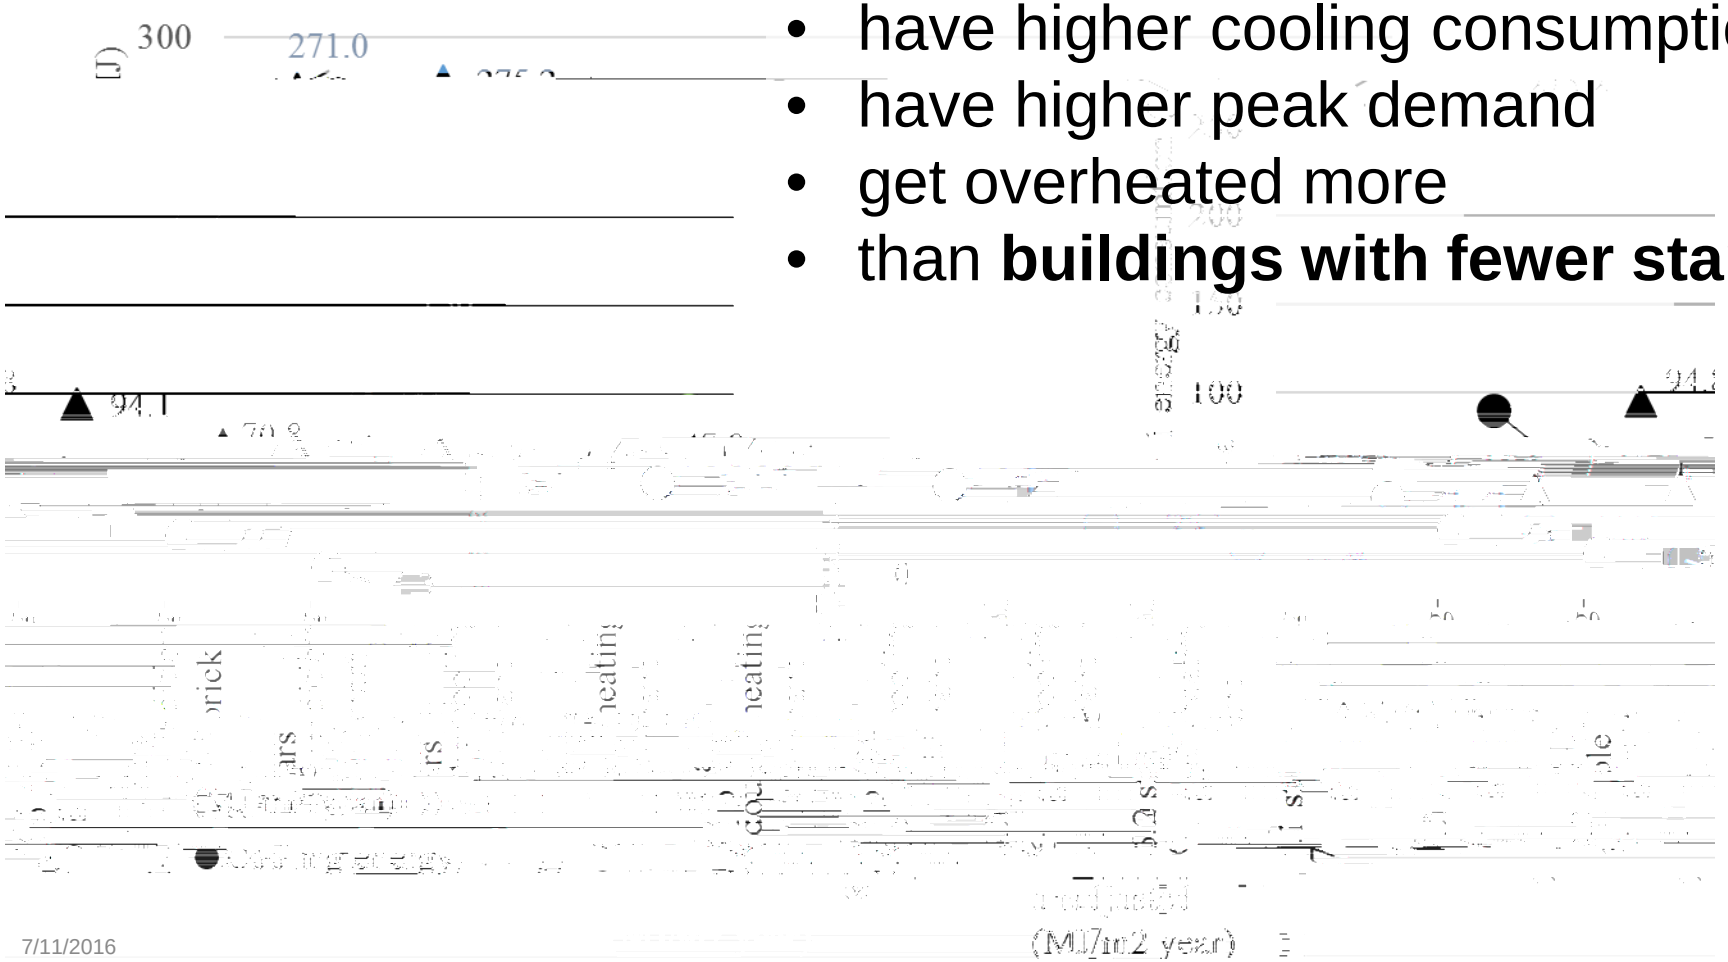
Results, online survey on heat stress resilience

- **Pre-existing health conditions** predicted higher vulnerability and they were oblivious of their vulnerability

- In contrast, **older people adapt more** and live in more resistant homes

- 6-9% of the population lives among poor housing conditions and suffers from **energy poverty**

Results: AccuRate simulation



Homes with more stars can

- have higher cooling consumption
- have higher peak demand
- get overheated more
- than **buildings with fewer stars**

Thank you for your attention!
